

Feedbacks to the prototypes:

1. Centralized Control Architecture (The "Double Start" Cognitive Load)

- *Problem Identified:* In the initial wireframes, both the iPhone and the Apple Watch featured a prominent "Start Session" button. Testers reported significant cognitive friction, expressing confusion over which device was supposed to initiate the tracking and uncertainty regarding whether pressing one would automatically trigger the other.
- *Implemented Solution:* We centralized the control architecture, establishing the iPhone as the primary "Local Brain." The start button was entirely removed from the Watch interface to eliminate ambiguity. Now, initiating the session on the iPhone sends a silent background command (sendMessage) that automatically wakes the Watch sensors. The Watch UI was simplified to act purely as a passive status indicator ("READY" / "SENSORS ACTIVE"), drastically reducing the user's setup time under stress.

2. Insufficient Post-Session Data Depth

- *Problem Identified:* The mobile prototype successfully displayed the AI-generated text report at the end of a session. However, users felt that while the text was helpful, the overall mobile report lacked the statistical depth and visual timelines needed to truly dissect their performance.
- *Implemented Solution:* This limitation drove the expansion of the platform into the Mac Dashboard. While the iPhone retains a quick summary, the desktop interface introduces deep data visualization. Users can now explore continuous line charts (AnxietyChartView and BPMChartView), pinpointing the exact minute a panic spike occurred. This allows for a much more comprehensive asynchronous analysis compared to the limited mobile screen space.

3. Absence of Long-Term Engagement

- *Problem Identified:* During the evaluation of the historical dashboard wireframes, users pointed out that after reviewing three or four sessions, the platform lacked intrinsic stimuli to keep them engaged and motivated to practice their public speaking in the long term.
- *Implemented Solution:* To address user retention, we integrated a Gamification layer. We designed a dedicated AchievementsView (Trophies board) within the dashboard. Users can now unlock specific milestones based on their biometric data—such as "Zen Master" for maintaining an average anxiety below 30%, or "Machine Gun" for hitting a pace peak over 180 WPM. This shifts the psychological framing of public speaking from a "stressful test" to an interactive "challenge to master."
